Keywords: genetic linkage mapping, single nucleotide polymorphism, quantitative trait loci, blackleg

Summary

An Illumina Infinium array comprising 5306 single nucleotide polymorphism (SNP) markers was used to genotype 175 individuals of a doubled haploid population derived from a cross between Skipton and Ag-Spectrum, two Australian cultivars of rapeseed (Brassica napus L.). A genetic linkage map based on 613 SNP and 228 non-SNP (DArT, SSR, SRAP and candidate gene markers) covering 2514.8 cM was constructed and further utilized to identify loci associated with flowering time and resistance to blackleg, a disease caused by the fungus Leptosphaeria maculans. Comparison between genetic map positions of SNP markers and the sequenced Brassica rapa (A) and Brassica oleracea (C) genome scaffolds showed several genomic rearrangements in the B. napus genome. A major locus controlling resistance to L. maculans was identified at both seedling and adult plant stages on chromosome A07. QTL analyses revealed that up to 40.2% of genetic variation for flowering time was accounted for by loci having quantitative effects. Comparative mapping showed Arabidopsis and Brassica flowering genes such as Phytochrome A/D, Flowering Locus C and agamous-Like MADS box gene AGL1 map within marker intervals associated with flowering time in a DH population from Skipton/Ag-Spectrum. Genomic regions associated with flowering time and resistance to L. maculans had several SNP markers mapped within 10 cM. Our results suggest that SNP markers will be suitable for various applications such as trait introgression, comparative mapping and high-resolution mapping of loci in B. napus.

Introduction

resistance, flowering time.

Rapeseed, Brassica napus L., (2n = 4x = 36, genome AACC) is grown mainly for the production of edible oil for human consumption and is the most important member of the Brassicaceae family, which consists of more than 3350 species. It originated as a result of interspecific hybridization between Brassica rapa (AA genome, $2n = 2 \times = 20$) and Brassica oleracea (CC genome, 2n = 2x = 18). Recently, the genomes of B. rapa and B. oleracea have been sequenced and annotated (Wang et al., 2011b, http://www.ocri-genomics.org/bolbase). Recent innovations in genome sequencing technologies and bioinformatics have made it possible to exploit molecular markers based on the variation in gene sequences. As a result, single nucleotide polymorphism (SNP) and insertion/deletion (InDEL) markers have been developed in various organisms, including B. napus (Ganal et al., 2009; Hu et al., 2012; Trick et al., 2009). SNPs are currently being recognized as the markers of choice for genetic diversity analysis, genome-wide association studies and genomic selection due to their abundance in the genome (every 44-75 bp), high rate of polymorphism and their suitability in assaying several thousand markers

in parallel on automated platforms (Ganal et al., 2012; Gore et al., 2009). Second-generation, high-throughput sequencing technologies, which are available on platforms provided by a number of companies such as Illumina, have been employed for genome sequencing in various crops including Brassicas (Bancroft et al., 2011; Michael and Alba, 2012; Trick et al., 2009; Wang et al., 2011b) and can be employed in the discovery of SNPs. Recently, several SNP markers have been identified in B. napus (Bus et al., 2013; Delourme et al., 2013; Durstewitz et al., 2010; Tollenaere et al., 2012; Trick et al., 2009) and further assayed for polymorphisms on various high-throughput platforms such as GoldenGate, Infinium and second-generation sequencing, permitting rapid scoring of several thousand markers in parallel (Ganal et al., 2012). Dalton-Morgan et al. (2014) developed an Infinium array comprising 5306 SNP markers (designated as the 6K_Evie B. napus chip) from B. napus short read sequence data. However, its utility in high-density map construction and identification of qualitative and quantitative trait loci in B. napus using genome-wide linkage analysis has yet to be explored.

Two Australian *B. napus* cultivars, Skipton (S) and Ag-Spectrum (AS), exhibit genetic variation for flowering time,
